MANIPAL UNIVERSITY JAIPUR
Department of Computer Science & Engineering

FINAL PROJECT REPORT

CSE3253 — DevOps [PE6]

Semester VI | Academic Year 2025–2026

Nagios Configuration Generator

Automated Generation of Nagios Monitoring Configuration Files

Category: Puppet/Monitoring | Difficulty: Intermediate

Student Name	Ayush Anand
Registration No.	23FE10CSE00339
Course	CSE3253 — DevOps [PE6]
Semester	VI (2025–2026)
Project Type	Puppet/Monitoring
Submitted To	Mr. Jay Shankar Sharma

1. Executive Summary

This report documents the design, development, and deployment of the Nagios Configuration Generator — a DevOps tooling project developed as part of CSE3253 (DevOps, PE6) at Manipal University Jaipur. The project addresses a common pain point in infrastructure operations: the manual, error-prone authoring of Nagios monitoring configuration files at scale.

The solution delivers a dual-interface tool — a Click-based CLI and a Flask web application — that reads structured YAML input or web form data, validates it through Pydantic models, and renders production-ready Nagios .cfg files using a Jinja2 templating engine. The entire stack is containerised with Docker, orchestrated with Kubernetes manifests, and gated by a GitHub Actions CI/CD pipeline that enforces code quality, automated testing, and Docker image verification on every commit.

All six primary milestones were achieved: core generation engine, CLI tooling, web UI with ZIP download, Docker containerisation, CI/CD pipeline, and full documentation. Test coverage exceeds 85%, build time is under 45 seconds, and the Docker image weighs approximately 150 MB.

2. Project Overview

2.1 Problem Statement

Nagios is one of the most widely deployed open-source infrastructure monitoring systems. However, configuring Nagios manually requires writing verbose define blocks for every host, service, contact, hostgroup, contact group, and command. A realistic production environment of 50+ servers translates into hundreds to thousands of configuration lines, making the process tedious, inconsistent, and difficult to version-control or audit.

There is no official tool that bridges structured input (YAML or web form) with valid, deployable Nagios .cfg output, leaving DevOps teams to rely on manual copy-paste or fragile custom scripts.

2.2 Objectives

- Automate Nagios .cfg file generation from structured YAML input
- Provide both a CLI tool and a browser-based web UI for different workflows
- Validate all input fields (IP addresses, hostnames, email addresses, threshold values) before generation
- Package the application with Docker for one-command deployment
- Implement a multi-stage CI/CD pipeline (lint → test → Docker build) via GitHub Actions
- Provide comprehensive documentation: README, user guide, design document, and project plan

2.3 Scope

The project covers the complete lifecycle from raw user input to deployable Nagios configuration. In scope: YAML-driven generation, web form generation, five configuration object types (hosts, services, contacts, contact groups, hostgroups, commands), Docker containerisation, Kubernetes deployment manifests, Jenkins pipeline, GitHub Actions pipeline, self-monitoring Nagios configs, and a full pytest test suite. Out of scope: direct integration with a live Nagios server, user authentication in the web UI, and database persistence.

3. Technology Stack

3.1 Core Application

Component	Technology	Version	Purpose
Language	Python	3.11	Primary implementation language
CLI Framework	Click	8.1.7	Command-line interface with sub-commands
Web Framework	Flask	3.0.0	Browser-based web UI and form handling
Templating Engine	Jinja2	3.1.2	Rendering Nagios .cfg files from templates
Data Validation	Pydantic v2	2.5.0	Field-level validation and data modelling
Config Format	YAML	PyYAML 6.0.1	Structured input format for CLI mode
WSGI Server	Gunicorn	21.2.0	Production web server
Testing	pytest	7.4.3	Unit, integration and CLI smoke tests
Linting	flake8	6.1.0	PEP 8 compliance and static analysis

3.2 DevOps Infrastructure

Tool	Category	Usage
Git	Version Control	Branching, commit conventions, PR workflow
GitHub Actions	CI/CD	Lint → Test → Docker Build pipeline on push/PR
Jenkins	CI/CD	Parameterised pipeline with staging/production stages
Docker	Containerisation	Multi-stage Dockerfile; ~150 MB final image
Docker Compose	Local Orchestration	One-command local stack with optional Nagios server
Kubernetes	Orchestration	Deployment, Service, ConfigMap manifests; 2 replicas
Nagios	Monitoring	Self-monitoring configs for the generator service itself

4. System Architecture

4.1 Layered Architecture

The application follows a clean, four-layer architecture that separates concerns and allows the CLI and web UI to share the same core engine:

- Interface Layer — Click CLI (YAML input) and Flask Web UI (HTML form input)
- Validation Layer — Standalone validators.py for raw-data pre-checks; Pydantic models for type-safe structural validation
- Generation Layer — NagiosGenerator loads Jinja2 templates, renders them with validated model data, and produces .cfg content
- Output Layer — File writes to disk (CLI), in-browser preview + ZIP download (Web UI)

4.2 Data Flow

Step	Action	Module
1	User provides YAML file (CLI) or submits web form (Web UI)	cli.py / web.py
2	Raw data is parsed: yaml.safe_load() or Flask request	cli.py / web.py
3	validate_yaml_input() pre-checks structure and field values	validators.py
4	NagiosConfig.from_dict() constructs a validated Pydantic model	models.py
5	NagiosGenerator.generate() renders all Jinja2 templates	generator.py
6	Output: .cfg files on disk (CLI) or ZIP download (Web UI)	generator.py

4.3 Module Descriptions

Module	Responsibility
models.py	Pydantic v2 models: Host, Service, Contact, ContactGroup, HostGroup, Command, NagiosConfig. Field validators enforce hostname regex, IP format, email regex, numeric ranges.
validators.py	Standalone functions for IP, hostname, email, address, threshold, and time-period validation. Used as a pre-check layer before Pydantic model construction.
generator.py	NagiosGenerator class: loads Jinja2 environment, maps templates to output filenames, renders .cfg content, writes files to disk, and creates ZIP archives.
cli.py	Click CLI with generate (YAML → .cfg files), validate (dry-run), and web (launch Flask) sub-commands. Exits with code 1 on any validation or generation error.

Module	Responsibility
web.py	Flask app with /, /generate (form → preview), and /download (form → ZIP) routes. Parses multi-value form fields for hosts, services, contacts, and contact groups.
config/config.py	Application-wide constants: default check periods, notification intervals, known Nagios time periods, and recognised check command names.

5. Key Features & Implementation

5.1 Dual-Interface Design

Both interfaces — CLI and Web UI — share the same NagiosGenerator engine, ensuring identical output regardless of input method.

- CLI: Three sub-commands — generate (YAML → .cfg files), validate (dry-run with detailed count output), and web (start Flask server). Built with Click for POSIX-compliant argument parsing.
- Web UI: Dark-themed glassmorphism design built with vanilla HTML/CSS/JS. Dynamic entry cards (add/remove hosts, services, contacts, contact groups) with badge counters. Result page shows per-file preview and a ZIP download button.

5.2 Input Validation

Validation happens at two levels, providing defence-in-depth against malformed input:

- Pre-validation (validators.py): Standalone functions check IP addresses (ipaddress module), hostnames (regex), email addresses (regex), and structural completeness (required fields present). Returns a list of error messages.
- Model validation (Pydantic v2): Field-level @field_validator decorators enforce types, ranges (max_check_attempts 1–100, notification_interval ≥ 0, intervals ≥ 1), and format constraints. Pydantic provides clear, user-friendly error messages.

5.3 Jinja2 Templating

Five .j2 templates correspond to five Nagios configuration file types. The template environment uses trim_blocks and lstrip_blocks for clean whitespace handling. Templates skip generation entirely when their corresponding data list is empty, avoiding the creation of empty .cfg files that would cause Nagios warnings.

5.4 Docker & Kubernetes

The Dockerfile uses a two-stage build: a builder stage installs all Python dependencies into /install, and a slim runtime stage copies only those packages — reducing the final image from ~900 MB to ~150 MB. A HEALTHCHECK pings the Flask root endpoint every 30 seconds. The docker-compose.yml includes an optional Nagios server profile (--profile full) that mounts generated configs directly into the Nagios container for immediate verification.

Kubernetes manifests provide: a Deployment (2 replicas, resource requests/limits, liveness and readiness HTTP probes), a NodePort Service (port 30500), and a ConfigMap for environment variables.

5.5 CI/CD Pipeline

Stage	Tool	Actions
Code Quality	GitHub Actions / Jenkins	flake8 linting with max-line-length=120
Unit Tests	pytest	models, validators, generator, CLI sub-commands
Integration Tests	pytest	End-to-end YAML → .cfg generation with file verification
CLI Smoke Test	GitHub Actions	validate + generate against sample_input.yaml; verify output files
Docker Build	GitHub Actions / Jenkins	Build image, start container, curl health check, inspect image size
Security Scan	Jenkins (trivy)	Vulnerability scan on built Docker image
Deploy Staging	Jenkins	docker-compose up on staging environment (conditional)
Deploy Production	Jenkins	kubectl apply with manual approval gate (conditional)

6. Testing

6.1 Test Structure

The test suite is organised into three categories under tests/:

- Unit Tests (tests/unit/): Cover validators.py (validate_ip_address, validate_hostname, validate_email, validate_address, validate_threshold, validate_check_period, validate_yaml_input), generator.py (generate, write, generate_zip, NagiosConfig.from_yaml), and cli.py (validate command, generate command, version flag).
- Integration Tests (tests/integration/): End-to-end test from sample_input.yaml through CLI generate to output .cfg files. Verifies exit code, file count, file content (define blocks), and non-empty output.
- CI Smoke Tests: CLI validate and generate are run against the sample YAML in both GitHub Actions and Jenkins pipelines, with file listing to verify output.

6.2 Test Results

Metric	Target	Achieved
Test Coverage	> 80%	85%+
Unit Tests	Pass all	All passing
Integration Tests	Pass all	All passing
CLI Smoke Test	Exit code 0	Exit code 0, 5 files generated
Docker Health Check	HTTP 200	HTTP 200 on port 5000

7. Project Structure

The repository follows the prescribed DevOps project structure:

8. Milestones & Deliverables

8.1 Project Milestones

Milestone	Description	Status
M1	Core generator produces valid hosts.cfg from YAML input	✓ Complete
M2	CLI tool with generate and validate commands working	✓ Complete
M3	Web UI form → generated config preview + ZIP download	✓ Complete
M4	Docker container builds and serves the web UI on port 5000	✓ Complete
M5	CI/CD pipeline passes (lint, test, docker-build)	✓ Complete
M6	Full documentation suite (README, user guide, design doc, plan)	✓ Complete

8.2 Performance Metrics

Metric	Target	Achieved
Build Time	< 2 minutes	~45 seconds
Test Coverage	> 80%	85%+
Config Generation Speed	< 1 second	~100 ms
Docker Image Size	< 200 MB	~150 MB
Pipeline Stages	≥ 4 stages	4 stages (GH Actions) / 7 stages (Jenkins)

9. Assessment Checklist

Repository Structure (1 Mark)

✓ Proper folder structure following prescribed template

✓ All required directories present (src, docs, infrastructure, pipelines, tests, monitoring)

✓ Clear organisation with descriptive naming conventions

Code Quality (2 Marks)

✓ Clean, readable code with descriptive variable and function names

✓ Comprehensive docstrings on all modules, classes, and public functions

✓ PEP 8 compliance enforced via flake8 (max-line-length=120) in CI

✓ Error handling: try/except around YAML parsing, Pydantic validation, and template rendering

Documentation (3 Marks)

✓ Comprehensive README with quick-start, CLI/Web UI reference, YAML format, Docker instructions

✓ Technical design document with architecture diagram, data flow, module descriptions, design decisions

✓ User guide covering all three CLI sub-commands, web UI steps, YAML format, and troubleshooting

✓ Project plan with timeline, milestones, risk analysis, and resource requirements

DevOps Implementation (3 Marks)

✓ CI/CD pipeline: GitHub Actions (lint → test → smoke test → Docker build) + Jenkinsfile

✓ Containerisation: multi-stage Dockerfile, docker-compose with health checks and volume

✓ Kubernetes: Deployment (2 replicas, resource limits, health probes), Service, ConfigMap

✓ Self-monitoring: Nagios .cfg files monitoring the generator's HTTP endpoint, process, disk, and CPU

✓ Security: Pydantic input sanitisation, no hardcoded secrets, environment-based config, minimal Docker image

Presentation (1 Mark)

✓ Repository and codebase ready for live demonstration

✓ sample_input.yaml provides an end-to-end demo in under 10 seconds

✓ Web UI provides a fully interactive demo without any setup

10. Challenges & Learnings

10.1 Technical Challenges

Challenge	Solution
Jinja2 whitespace control in Nagios configs	Used trim_blocks and lstrip_blocks on the Jinja2 Environment. Nagios is sensitive to trailing whitespace and blank lines within define blocks.
Pydantic v2 migration (from v1 patterns)	Adopted @field_validator (classmethod) syntax throughout models.py. Pydantic v2's stricter mode required explicit type annotations on all fields.
Multi-stage Docker build size optimisation	Separated dependency installation (builder stage) from the runtime image. Used python:3.11-slim as the base, reducing the image from ~900 MB to ~150 MB.
Web form multi-value field parsing	Flask's request.form.getlist() with array notation (e.g., host_name[]) was used to collect all entries for each dynamic section added by the JavaScript UI.
Gunicorn in Docker vs Flask debug mode	Ensured the Dockerfile CMD uses gunicorn (production), while the CLI web sub-command optionally enables Flask debug mode only when --debug flag is passed.

10.2 Key Learnings

- Pydantic v2 significantly simplifies data validation in Python with declarative, reusable field validators that produce structured, user-friendly error messages.
- Multi-stage Docker builds are essential for production-grade images — separating the build environment from the runtime environment cuts image size by 80%+ in Python projects.
- Jinja2 is a natural fit for configuration file generation: its loop and conditional constructs map directly to Nagios' repetitive define block structure.
- A dual CI/CD setup (GitHub Actions for developer feedback + Jenkins for deployment control) provides both speed (fast PR checks) and governance (manual production approval gates).
- Writing tests before or during development (rather than after) surfaced edge cases in the validation logic early — particularly around address validation (IP vs hostname).
- Kubernetes health probes (liveness + readiness) are essential for production reliability and should be designed alongside the application, not added as an afterthought.

11. Future Enhancements

- Live Nagios Validation: Integrate with the Nagios Core nagios -v command to validate generated configs against a running Nagios instance before download.
- Authentication: Add Flask-Login with session management to protect the web UI in multi-user environments.
- Database Persistence: Store generated configurations in PostgreSQL with history/versioning, allowing users to retrieve and diff previous configs.
- Terraform & Ansible Integration: Export generated host lists as Terraform resource definitions or Ansible inventory files for cross-tool compatibility.
- Import from Existing Configs: Parse existing Nagios .cfg files and reverse-generate YAML, enabling adoption in environments with legacy manual configs.
- OpenAPI Specification: Add a REST API layer with FastAPI and generate OpenAPI docs to allow programmatic config generation from other DevOps tools.

12. Conclusion

The Nagios Configuration Generator successfully achieves all stated objectives. It eliminates the manual, error-prone process of writing Nagios .cfg files by providing a validated, template-driven generation pipeline accessible through both a CLI and a web interface. The project demonstrates practical application of the core DevOps curriculum: version control with Git, CI/CD automation with GitHub Actions and Jenkins, containerisation with Docker, orchestration with Kubernetes, monitoring with Nagios, and Python application development with modern frameworks (Flask, Click, Pydantic, Jinja2).

All six milestones are complete, test coverage exceeds the 80% target, the CI/CD pipeline is fully operational, and the Docker image meets the size constraint. The project is ready for evaluation, live demonstration, and potential extension into a production-grade infrastructure tooling utility.
